

UI/UX Testing

UI testing focuses on the layout and looks of the application. It ensures the elements like button, button size, font, menu, alignment, etc. are functional and meets the requirements or not. Eg: Menu bar is visible and is working or not.

UX testing focuses on the overall user-experience on the system. It ensures application is easy to use, everything is functional from the end-user's perspective. Eg: Checking if the user can navigate through one page to another without lagging.

UIUX testing focuses on the usability, navigation, smoothness, clear layout, etc.

Cross-Browser Testing

Cross-browser testing is testing done across different browsers like brave, opera, safari, etc. It ensures the program or the system works in every browser or not. Eg: a submit button that is working perfectly in safari may not work in chrome. So, this testing ensures every functions are working good. It tests aspects like CSS rendering, JavaScript behavior, cookies, extensions, etc. It's very important as it:

- Prevents layout breaking issues
- Prevents functionality issues
- Expands the reach. Not every user use the same browser.
- Consistent performance

Responsiveness Design Testing.

Responsiveness testing is the testing done to make sure everything works very smoothly without being harmed across different platforms and devices like laptop, PC, mobile phones.

It makes sure the system adapts well in all of these devices. A site may look good in desktop but might break in the phone. This testing covers things like button is stable and working, no overlapping of elements to each other.
