

Regression Testing

Regression testing is the process of re-running test cases to ensure recent code changes have not broken previous functionality. Eg: a calculator app supports addition, subtraction. After introducing Standard deviation feature, it doesn't break the addition and subtraction feature. It's main purpose is to maintain software stability after updates.

Importance of Re-testing

- **Verify Fixes:** Ensures the developer's fix truly resolved the reported bug.
- **Prevent Recurrence:** Confirms the same issue doesn't appear again under similar conditions.
- **Quality Assurance:** Builds confidence before release or deployment.
- **Avoid Side Effects:** Detects new issues introduced unintentionally by the fix.
- **Builds Stakeholder Confidence:** Successful retesting provides assurance to stakeholders that problems have been solved and the software is reliable, building confidence in the product's quality.

Smoke vs Sanity vs Regression Testing
