

Test Execution Process

The process of executing the tests to verify that the functions, modules provide expected outcome and meet the client's requirements is called test execution process. It comes under one the phases of STLC. It helps to ensure:

- project runs smoothly.
- requirements are correctly met with design and architecture.
- application's competency.

The phases of test execution process are:

- **Creation of test cases:** Here, the tester creates test cases. The created test case is not repeated again and covers all the scenarios.
- **Test Cases execution:** Quality Analyst team does either manual or automated testing however both the testing is preferable for accuracy.
- **Validating test results:** Check whether the executed test cases are achieves the expected result or not. The time required to complete each test case is recorded. If any of the test case is unsatisfactory, then it is sent to the development team for validation.

Defect Reporting Process

Defect in the software have tons of names like errors, bugs, fault, issue and many others although they all mean the same thing. A defect report is a document that has detailed information relating to the defects of system like what type of defects, it's severity, what defects are identified, what are to be solved and what are the expected results. It is created by the QA team and also by the end-users. The developer team then reads the report and reproduces the defects on the software product by follow by the steps mentioned in the

report. After that, the developer fixes the defects in order to get the desired outcome specified in the report.

A Defect Report document generally consists of:

Defect ID, Defect Description, Steps, Expected Result, Actual Result, Severity, Priority, Comments, Attachments (if any)

Test Closure Activities

Test closure activities are performed at the end of the testing process. It is usually performed after the product is delivered. After the test execution phase is completed, test closure begins with 4 key groups:

- **Checking for completion of tests:** Test Manager ensures every test work has actually been completed. All bugs must be corrected.
- **Handing over test objects:** Known bugs must be given to the maintenance team. Manual and Automated tests should be recorded.
- **Learning experience:** Here, the discussion of lessons learned is done. It focuses on ensuring good culture is implemented.
- **Archiving:** Test documents and reports are archived in the system.
