

Exploratory testing approach

Exploratory testing is a type of testing in which the tester is free to explore and test any features in the system without any requirement or todos. It is a black box testing technique.

- Developers learn, test, and design test cases simultaneously.
- There are no pre-written test cases to explore the system freely.
- It relies on the tester's intuition, experience, and curiosity.
- Developers observe the system, note unusual behavior, usability issues, and performance problems.

When TO Use

Documenting Exploratory findings

Exploratory testing is a structured and uniform exploration. The findings should be well documented in order to observe and analyze for future necessities. Hence, a developer/

tester must ensure that everything is well documented for others to understand and resolve or make improvements.

A good log includes:

- Tester name
- Date & time
- Module / Feature explored
- Objective
- Test environment / build version
- Observations (defects, UI issues, performance notes)
- Comments
